

numpy intro

ndarray → support for math operations

scalars in numpy can be uint8, int8, uint16, ...

example:

$\left\{ \begin{array}{l} s = \text{np.array}(5) \rightarrow \text{only holds a scalar} \\ s.\text{shape} \rightarrow () \rightarrow 0\text{-dim} \\ x = s + 3 \end{array} \right.$

$\left\{ \begin{array}{l} v = \text{np.array}([1, 2, 3]) \\ v.\text{shape} \rightarrow (3,) \\ v[1] \rightarrow 2, \quad v[1:] \rightarrow [2, 3] \end{array} \right.$

$\left\{ \begin{array}{l} m = \text{np.array}([[1, 2, 3], [4, 5, 6], [7, 8, 9]]) \\ m.\text{shape} \rightarrow (3, 3) \end{array} \right.$

reshaping:

$v = \text{np.array}([1, 2, 3, 4]) \quad (4,)$

$x = v.\text{reshape}(1, 4) \quad (1, 4)$

element-wise matrix operations:

$$2 + \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} = \begin{bmatrix} 2+1 & 2+2 \\ 2+3 & 2+4 \end{bmatrix}$$

$$x = \text{np.multiply}(\text{some_array}, 5) \quad \equiv \quad x = \text{some_array} * 5$$

$m * 0 \rightarrow$ no matter the dims of m ,
all of the elements become zero.

$m * m \rightarrow$ element-wise multiplication

Matrix product:

$$\text{np.matmul}(A, B)$$

$$AB \neq BA$$

Matrix transpose:

$$\text{np.transpose}(a) \quad \text{or} \quad a.T$$
